2. Which	of those st	atements about mini-batch gradient descent do you agree with?	
O		tion of mini-batch gradient descent (computing on a single mini-batch) is faster	than one iteration of batch gradier
Corr	ect		
		one epoch (one pass through the training set) using mini-batch gradient descen ch gradient descent.	t is faster than training one epoch
		ld implement mini-batch gradient descent without an explicit for-loop over diffencesses all mini-batches at the same time (vectorization).	erent mini-batches, so that the

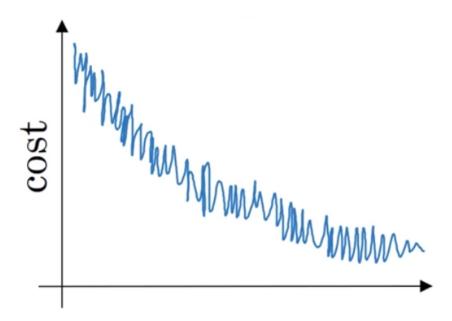

Why is the best mini-batch size usually not 1 and not m, but instead something in-between?

1/1 point

If the mini-batch size is 1, you lose the benefits of vectorization across examples in the mini-batch.

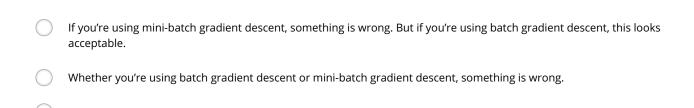

# Correct Correct Optimization algorithms Quiz, 10 questions If the mini-batch size is m, you end up with stochastic gradient descent, which is usually slower than mini-batch gradient descent. Un-selected is correct If the mini-batch size is m, you end up with batch gradient descent, which has to process the whole training set before making progress. Correct If the mini-batch size is 1, you end up having to process the entire training set before making any progress. Un-selected is correct

4. Suppose your learning algorithm's cost J, plotted as a function of the number of iterations, looks like this:

Which of the following do you agree with?

point

Whether you're using batch gradient descent or mini-batch gradient descent, this looks acceptable.

## Optimization algorithms

94 you're using mini-batch gradient descent, this looks acceptable. But if you're using batch gradient descent, something is

Correct

5.

Suppose the temperature in Casablanca over the first three days of January are the same:

Jan 1st: 
$$heta_1=10^oC$$

Jan 2nd:  $heta_2 10^o C$ 

(We used Fahrenheit in lecture, so will use Celsius here in honor of the metric world.)

Say you use an exponentially weighted average with  $\beta=0.5$  to track the temperature:  $v_0=0$ ,  $v_t=\beta v_{t-1}+(1-\beta)\theta_t$ . If  $v_2$  is the value computed after day 2 without bias correction, and  $v_2^{corrected}$  is the value you compute with bias correction. What are these values? (You might be able to do this without a calculator, but you don't actually need one. Remember what is bias correction doing.)

$$v_2=10$$
,  $v_2^{corrected}=7.5$ 

$$v_2=7.5$$
 ,  $v_2^{corrected}=10$ 

### Correct

$$igcup v_2=10$$
,  $v_2^{corrected}=10$ 

$$v_2=7.5$$
,  $v_2^{corrected}=7.5$ 

Which of these is NOT a good learning rate decay scheme? Here, t is the epoch number.

$$lpha=e^tlpha_0$$

### Correct

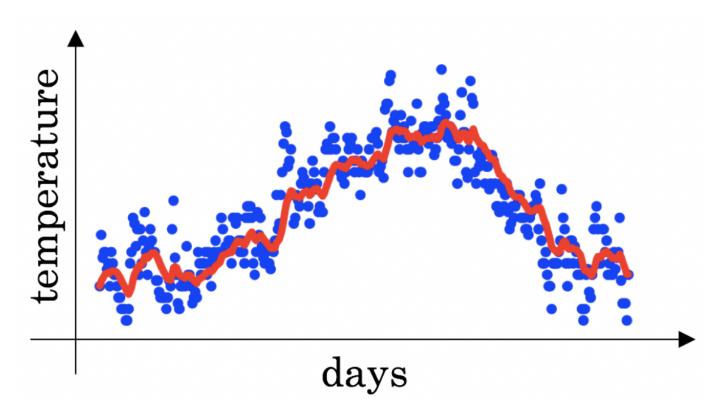

$$lpha=rac{1}{1+2*t}lpha_0$$

$$lpha = 0.95^t lpha_0$$

$$\alpha = \frac{1}{\sqrt{t}} \alpha_0$$

7.

You use an exponentially weighted average on the London temperature dataset. You use the following to track the temperature:  $v_t = \beta v_{t-1} + (1-\beta)\theta_t$ . The red line below was computed using  $\beta = 0.9$ . What would happen to your red curve as you vary  $\beta$ ? (Check the two that apply)

### **Un-selected is correct**

### Correct

True, remember that the red line corresponds to  $\beta=0.9$ . In lecture we had a green line \$\$\beta=0.98\$) that is slightly shifted to the right.

 $\hfill \Box$  Decreasing  $\beta$  will create more oscillation within the red line.

### Correct

True, remember that the red line corresponds to  $\beta=0.9$ . In lecture we had a yellow line \$\$\beta=0.98\$ that had a lot of oscillations.

9

Suppose batch gradient descent in a deep network is taking excessively long to find a value of the parameters that achieves a small value for the cost function  $\mathcal{J}(W^{[1]},b^{[1]},...,W^{[L]},b^{[L]})$ . Which of the following techniques could help find parameter values that attain a small value for  $\mathcal{J}$ ? (Check all that apply)

Correct
